33-1

Operational Laws

- Relationships that do not require any assumptions about the distribution of service times or inter-arrival times.
- □ Identified originally by Buzen (1976) and later extended by Denning and Buzen (1978).
- \Box **Operational** \Rightarrow Directly measured.

Operationally testable assumptions

- \Rightarrow assumptions that can be verified by measurements.
- > For example, whether number of arrivals is equal to the number of completions?
- > This assumption, called job flow balance, is operationally testable.
- A set of observed service times is or is not a sequence of independent random variables is not is not operationally testable.

©2012 Rai Jain

Operational Quantities Quantities that can be directly measured Black Box $T = Observation interval <math>A_i = Number \text{ of arrivals}$ $C_i = Number of completions <math>B_i = Busy \text{ time } B_i$ $Arrival Rate \lambda_i = \frac{Number \text{ of arrivals}}{Time} = \frac{A_i}{T}$ Throughput $X_i = \frac{Number \text{ of completions}}{Time} = \frac{C_i}{T}$ Utilization $U_i = \frac{Busy \text{ Time}}{Total \text{ Time}} = \frac{B_i}{T}$ Mean service time $S_i = \frac{Total \text{ time Served}}{Number \text{ served}} = \frac{B_i}{C_i}$ UC Berkeley, Fall 201233.4

Utilization Law

Utilization
$$U_i = \frac{\text{Busy Time}}{\text{Total Time}} = \frac{B_i}{T}$$

 $= \frac{C_i}{T} \times \frac{B_i}{C_i} = \frac{\text{Completions}}{\text{Time}} \times \frac{\text{Busy Time}}{\text{Completions}}$
 $= \text{Throughput} \times \text{Mean Service Time} = X_i S_i$
This is one of the operational laws
Operational laws are similar to the elementary laws of motion For example,

 $d = \frac{1}{2}at^2$

□ Notice that distance *d*, acceleration *a*, and time *t* are operational quantities. No need to consider them as expected values of random variables or to assume a distribution.

UC Berkelev, Fall 2012

33-5

Example 33.1

- Consider a network gateway at which the packets arrive at a rate of 125 packets per second and the gateway takes an average of two milliseconds to forward them.
- **D** Throughput X_i = Exit rate = Arrival rate = 125 packets/second
- \Box Service time $S_i = 0.002$ second
- **Utilization** $U_i = X_i S_i = 125 \times 0.002 = 0.25 = 25\%$
- □ This result is valid for any arrival or service process. Even if inter-arrival times and service times to are not IID random variables with exponential distribution.

33-6

Forced Flow Law

- □ Relates the system throughput to individual device throughputs.
- □ In an open model,

System throughput = # of jobs leaving the system per unit time

- □ In a closed model, System throughput = # of jobs traversing OUT to IN link per unit time.
- \Box If observation period T is such that $A_i = C_i$ \Rightarrow Device satisfies the assumption of *job flow balance*.
- \Box Each job makes V, requests for *i*th device in the system

$$\Box \quad C_i = C_0 V_i \text{ or } V_i = C_i / C_0 V_i \text{ is called visit ratio}$$

$$\Box \quad \text{System throughput } X = \frac{\text{Jobs completed}}{\text{Total time}} = \frac{C_0}{T}$$

UC Berkeley, Fall 2012

Forced Flow Law (Cont)

 \Box Throughput of *i*th device:

Device Throughput
$$X_i = \frac{C_i}{T} = \frac{C_i}{C_0} \times \frac{C_0}{T}$$

□ In other words:

$$X_i = XV_i$$

□ This is the **forced flow law**.

UC Berkeley, Fall 2012

©2012 Rai Jair

Bottleneck Device

• Combining the forced flow law and the utilization law, we get:

Utilization of
$$i^{\text{th}}$$
 device $U_i = X_i S_i$
= $X V_i S_i$
 $U_i = X D_i$

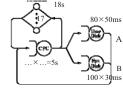

- □ Here $D_i = V_i S_i$ is the total service demand on the device for all visits of a job.
- □ The device with the highest D_i has the highest utilization and is the **bottleneck device**.

UC Berkeley, Fall 2012

33-9

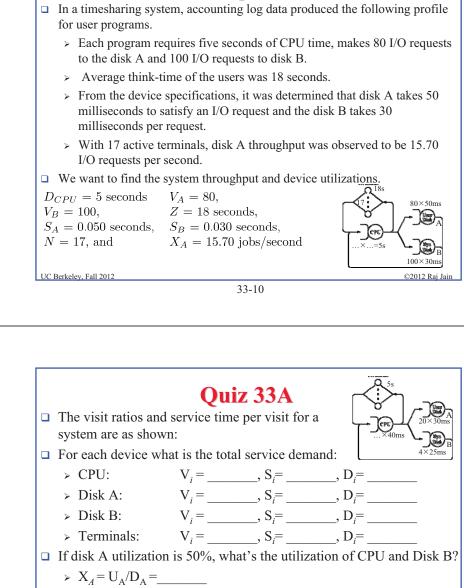

Example 33.2 (Cont)

 $\begin{array}{ll} D_{CPU} = 5 \; {\rm seconds} & V_A = 80, \\ V_B = 100, & Z = 18 \; {\rm seconds}, \\ S_A = 0.050 \; {\rm seconds}, & S_B = 0.030 \; {\rm seconds}, \\ N = 17, \; {\rm and} & X_A = 15.70 \; {\rm jobs/second} \end{array}$

©2012 Rai Jair

□ Since the jobs must visit the CPU before going to the disks or terminals, the CPU visit ratio is: $V_{CPU} = V_A + V_B + 1 = 181$ $D_{CPU} = 5$ seconds $D_A = S_A V_A = 0.050 \times 80 = 4$ seconds $D_B = S_B V_B = 0.030 \times 100 = 3$ seconds □ Using the forced flow law, the throughputs are: $X = \frac{X_A}{V_A} = \frac{15.70}{80} = 0.1963$ jobs/second $X_{CPU} = XV_{CPU} = 0.1963 \times 181$ = 35.48 requests/second $X_B = XV_B = 0.1963 \times 100$ = 19.6 requests/second □ Using the utilization law, the device utilizations are: $U_{CPU} = XD_{CPU} = 0.1963 \times 5 = 98\%$ $U_A = XD_A = 0.1963 \times 4 = 78.4\%$ $U_B = XD_B = 0.1963 \times 3 = 58.8\%$ UC Berkelev, Fall 2012 ©2012 Rai Jain

Example 33.2

$$\rightarrow U_{CPU} = X D_{CPU} =$$

$$\succ$$
 U_B = X D_B = ____

- □ What is the bottleneck device?
- $(Key: U_i = X_i S_i = XD_i, D_i = S_i V_i, X = X_i/V_i)$

©2012 Rai Jain

Transition Probabilities

- p_{ij} = Probability of a job moving to jth queue after service completion at ith queue
- Visit ratios and transition probabilities are equivalent in the sense that given one we can always find the other.

□ In a system with job flow balance:
$$C_j = \sum_{i=0}^{m} C_i p_{ij}$$

- $i = 0 \Rightarrow$ visits to the outside link
- □ p_{i0} = Probability of a job exiting from the system after completion of service at *i*th device

Dividing by
$$C_0$$
 we get:

$$V_j = \sum_{i=0}^{m} V_i p_{ij}$$

UC Berkeley, Fall 2012

C Berkeley Fall 20

```
33-15
```

Transition Probabilities (Cont)

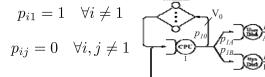

□ The above probabilities apply to exit and entrances from the system (*i*=0), also. Therefore, the visit ratio equations become:

$$1 = V_1 p_{10} \implies V_1 = \frac{1}{p_{10}}$$
$$V_1 = 1 + V_2 + V_3 + \dots + V_M$$
$$V_j = V_1 p_{1j} = \frac{p_{1j}}{p_{10}} \quad j = 2, 3, \dots, M$$

□ Thus, we can find the visit ratios by dividing the probability p_{1j} of moving to j^{th} queue from CPU by the exit probability p_{10} .

Transition Probabilities (Cont)

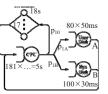

- □ Since each visit to the outside link is defined as the completion of the job, we have: $V_0 = 1$
- □ These are called visit ratio equations
- In central server models, after completion of service at every queue, the jobs always move back to the CPU queue:

UC Berkeley, Fall 2012

33-16

Example 33.3

02012 P

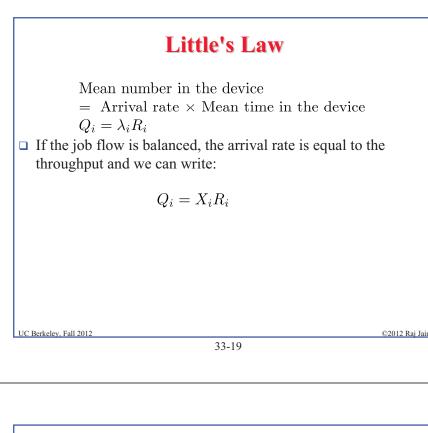

- □ Consider the queueing network:
- □ The visit ratios are V_A =80, V_B =100, and V_{CPU} =181.
- □ After completion of service at the CPU the probabilities of the job moving to disk A, disk B, or terminals are 80/181, 100/181, and 1/181, respectively. Thus, the transition probabilities are p_{1A}=0.4420, p_{1B}=0.5525, and p₁₀=0.005525.
- □ Given the transition probabilities, we can find the visit ratios by dividing these probabilities by the exit probability (0.005525):

$$V_A = \frac{p_{1A}}{p_{10}} = \frac{0.4420}{0.005525} = 80$$

$$V_B = \frac{p_{1B}}{p_{10}} = \frac{0.5525}{0.005525} = 100$$

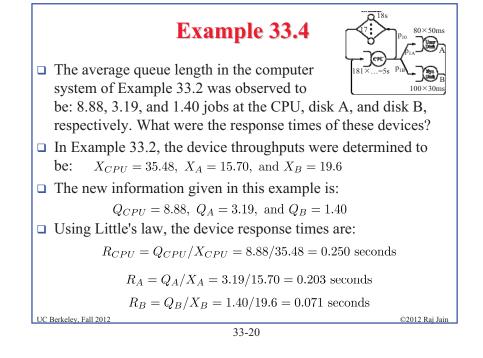

$$UC \text{ Berkeley, Fall 2012} \quad V_{CPU} = 1 + V_A + V_B = 1 + 80 + 100 = 181$$
(C2012 Raj Jain

General Response Time Law

□ There is one terminal per user and the rest of the system is shared by all users. □ Applying Little's law to the central subsystem: O = XRCentral subsysten □ Here. \Box Q = Total number of jobs in the system \square *R* = system response time \Box X = system throughput $Q = Q_1 + Q_2 + \dots + Q_M$ $XR = X_1R_1 + X_2R_2 + \dots + X_MR_M$ ©2012 Rai Jain UC Berkeley, Fall 2012 33-21

General Response Time Law (Cont)

©2012 Raj Jain

$$XR = X_1R_1 + X_2R_2 + \dots + X_MR_M$$

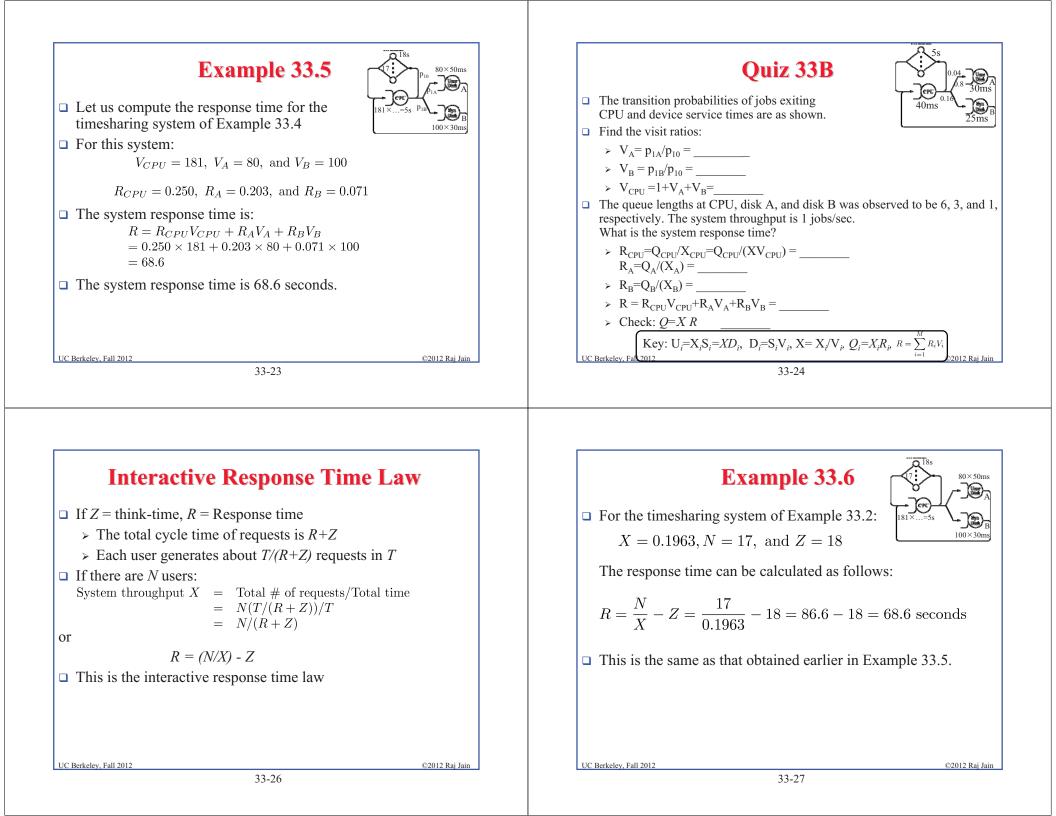

• Dividing both sides by X and using forced flow law:

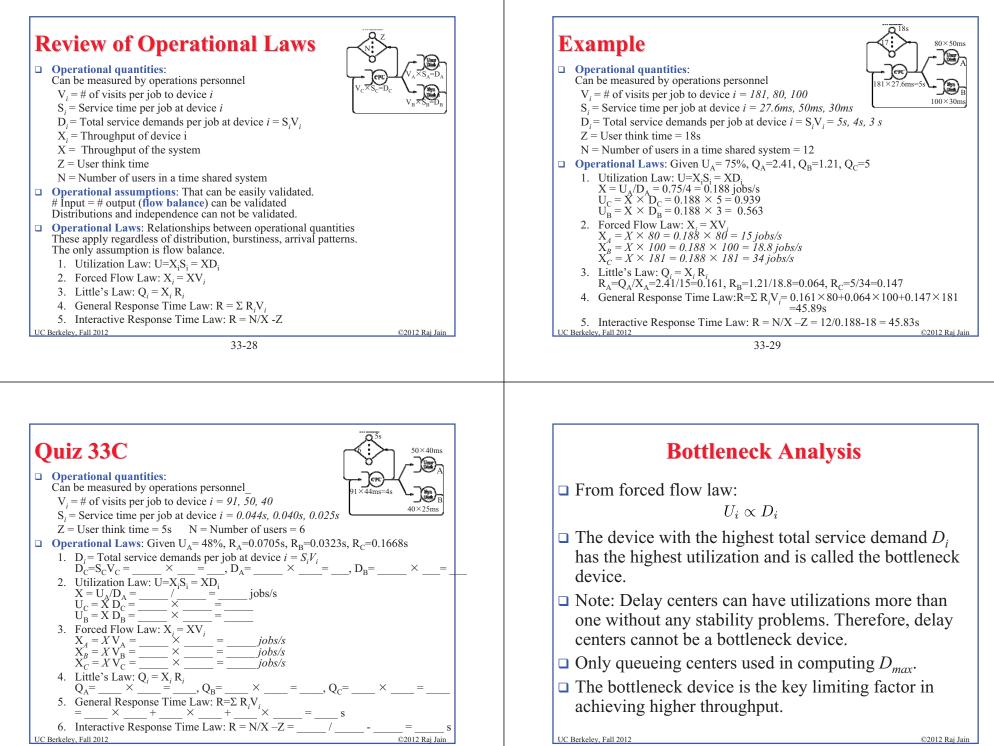

$$R = V_1R_1 + V_2R_2 + \dots + V_MR_M$$

• or,

$$R = \sum_{i=1}^M R_iV_i$$

• This is called the **general response time law**.

33-37

Bottleneck Analysis (Cont)

- Improving the bottleneck device will provide the highest payoff in terms of system throughput.
- Improving other devices will have little effect on the system performance.
- □ Identifying the bottleneck device should be the first step in any performance improvement project.

UC Berkeley, Fall 2012

33-38

Asymptotic Bounds: Proof

- □ The asymptotic bounds are based on the following observations:
 - 1. The utilization of any device cannot exceed one. This puts a limit on the maximum obtainable throughput.
 - 2. The response time of the system with N users cannot be less than a system with just one user. This puts a limit on the minimum response time.
 - 3. The interactive response time formula can be used to convert the bound on throughput to that on response time and vice versa.

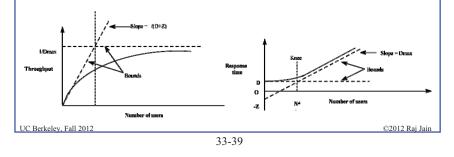

Asymptotic Bounds

□ Throughput and response times of the system are bound as follows: 1 N

$$X(N) \le \min\{\frac{1}{D_{max}}, \frac{1}{D+Z}\}$$

$$R(N) \ge max\{D, ND_{max} - Z\}$$

□ Here, $D = \sum D_i$ is the sum of total service demands on all devices except terminals.

Proof (Cont)

1. For the bottleneck device *b* we have:

$$U_b = XD_{ma}$$

Since U_b cannot be more than one, we have: $XD_{max} \leq 1$

$$X \le \frac{1}{D_{max}}$$

2. With just one job in the system, there is no queueing and the system response time is simply the sum of the service demands:

$$R(1) = D_1 + D_2 + \dots + D_M = D$$

With more than one user there may be some queueing and so the response time will be higher. That is:

 $R(N) \ge D$
